# Delayed Onset Allergy Testing

The two types of allergy responses are immediate and delayed. The immediate reaction response is when we eat something and break out in a rash in less than an hour. The **delayed reaction response (LRA - Lymphocyte Response Assay Test)** begins two hours to four days after the exposure and the inflammation can last up to three weeks.

When we come in contact, breath, or digest an allergen 10's of millions of white blood cells are made very rapidly, within minutes. It is the rate of explosion of the white blood cells that determines if the symptoms will happen immediately or are **delayed, resulting in an immune response.**

**Hidden allergies** can cause **autoimmune conditions, breathing issues, digestive issue, inflammation, and skin conditions.**

ELISA/ACT Biotechnologies pioneered the most accurate and thorough delayed onset allergy test called the LRA. The lab can measure **over 400** items including **additives, chemicals, colorings, foods, molds, preservatives, and toxic metals.**

## History of LRA Test by Elisa/ACT

Dr. Jaffe worked as a Researcher specializing in blood clots and strokes at the **National Institute of Health**. He used his background and collaborated with another researcher at **St. Louis Medical School**. Dr. Jaffe furthered their research and later patented a new method (**LRA - Lymphocyte Response Assay Test**) to view white blood cells reacting in the same way they would inside your blood stream and to identify causes of inflammation.

**Inflammation is the inability to repair.** If we can repair, we can get healthy.

This research breakthrough resulted in the **LRA - Lymphocyte Response Assay Test** we use at this office from **ELISA/ACT**
